

How to install, anaconda, tellurium and sbstoat

Install anaconda

First install anaconda from <https://www.anaconda.com/products/individual>
I recommend the graphical installer if you have a choice.

create a python 3.6 environment

To do this open a terminal (osx / linux) or the powershell in anaconda navigator (windows).

type in the following:

```
conda create -n py36 python=3.6.5
```

use anaconda navigator to activate the py36 environment if it isn't already activated.
(you can do this in the home tab using the applications on combo box)

Find the spyder app in the home tab and click install. After it has installed click launch.

(if spyder fails to install / launch you may need to go into the environments tab and delete

the py36 environment. You should then recreate the py36 environment using the create

button. (remember to select python 3.6 in the combo box in the dialog that pops up))

installing tellurium

When spyder has finished launching click in the console window and type the following

in after the in prompt:

```
!pip install tellurium
```

installing sbstoat

After tellurium has finished installing at the new in prompt type in:

```
!pip install SBstoat
```

installing seaborn

After sbstoat has finished installing at the new in prompt type in:

```
!pip install seaborn
```
